Lab Overview

This lab manual demonstrates how **Vibe Power Apps** enables you to build a Device Ordering app for your team using natural language guidance, AI-assisted UI generation, and automated logic creation, backed by robust data storage on Dataverse, fully supported with built-in security, RBAC, and scale.

Core concepts

Vibe apps bring together:

- **Agents** for generating UI, logic, and data, resulting in a full-stack React app
- **Dataverse** as the primary data store
- **Managed Platform** for scaled deployment and robust governance

Concept	Why it matters
Agent generated UI	Agents accelerate app delivery by generating pages, forms, and logic from natural language descriptions. It reduces development effort.
Business logic via NL	App agent can create patterns, validation, and conditional formatting by interpreting user intent, enabling rapid automation without writing formulas manually.
ALM	Every app built using Vibe lives in a Dataverse Solution by default. Move ahead with confidence and deploy your Vibe solution to downstream environments.

Documentation & learning resources

[Overview of the new Power Apps vibe experience - Power Apps]

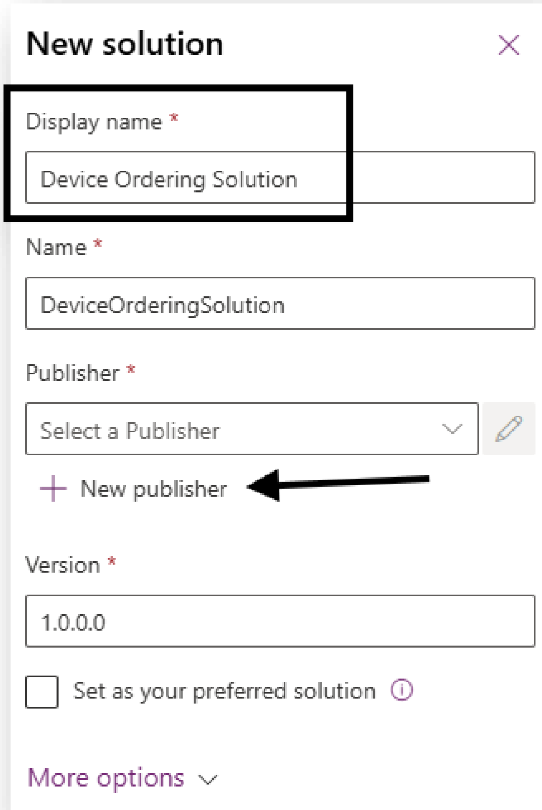
[Known Limitations]

Prerequisites

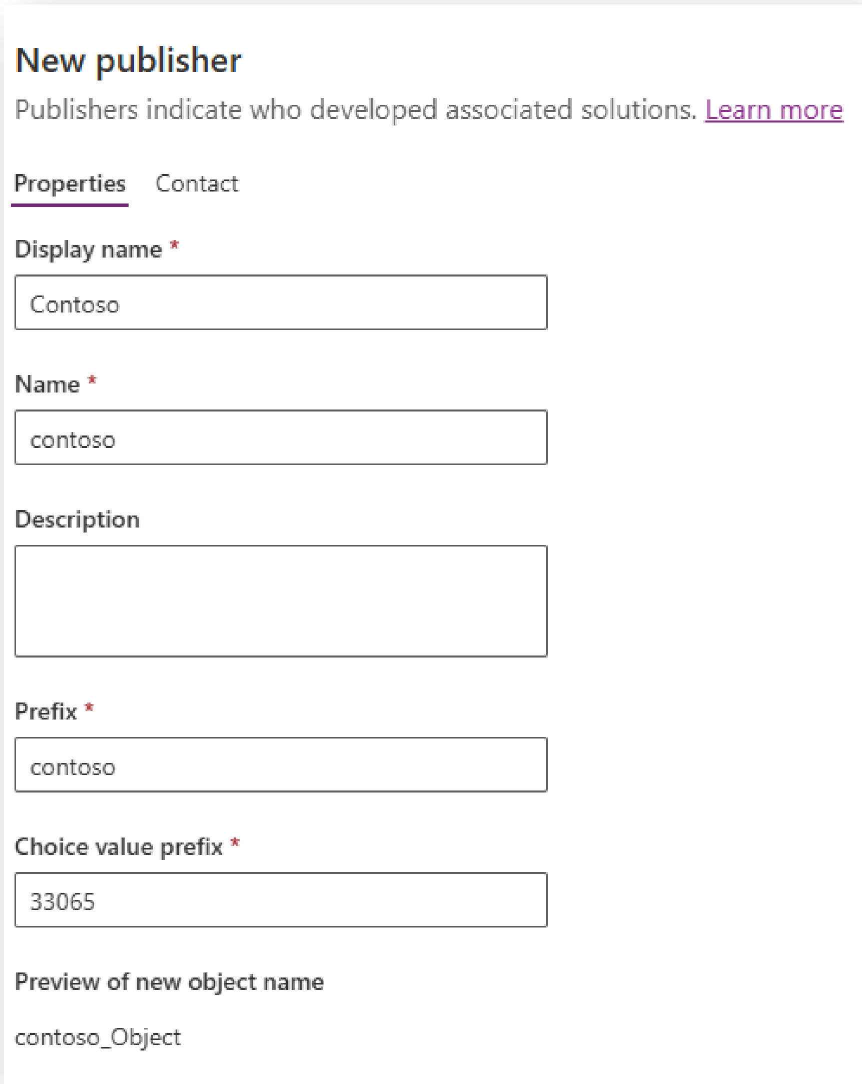
[Overview of the new Power Apps vibe experience - Power Apps]

Lab Steps

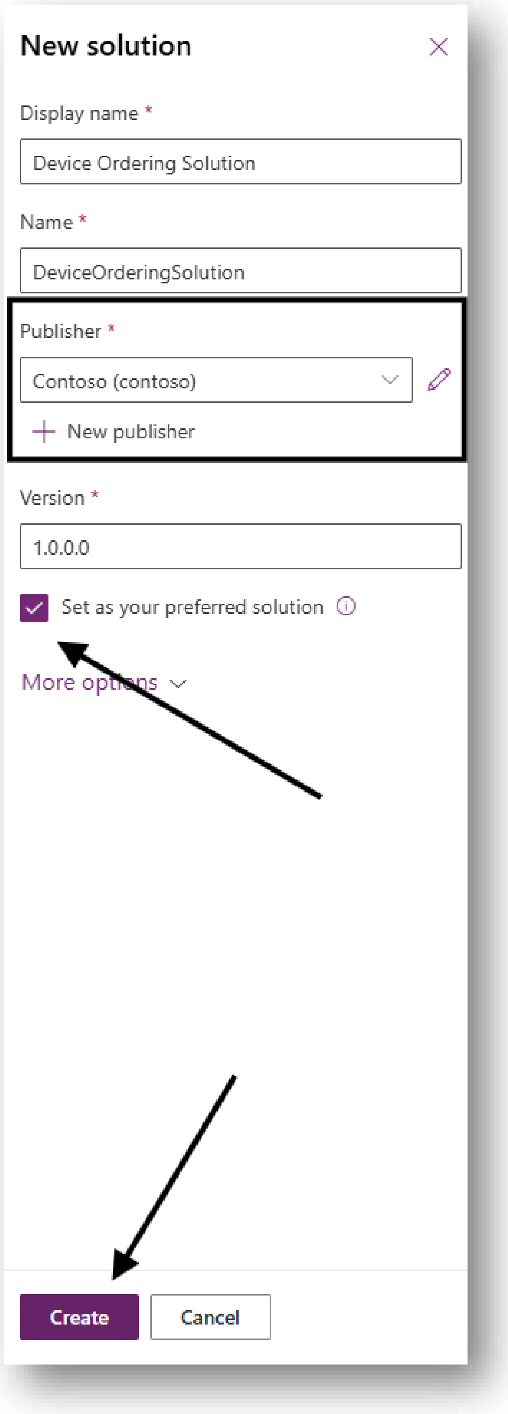
1. Create a new solution in Power Apps named “Device Ordering Solution”.



2. Create a new publisher named “Contoso” and click Save

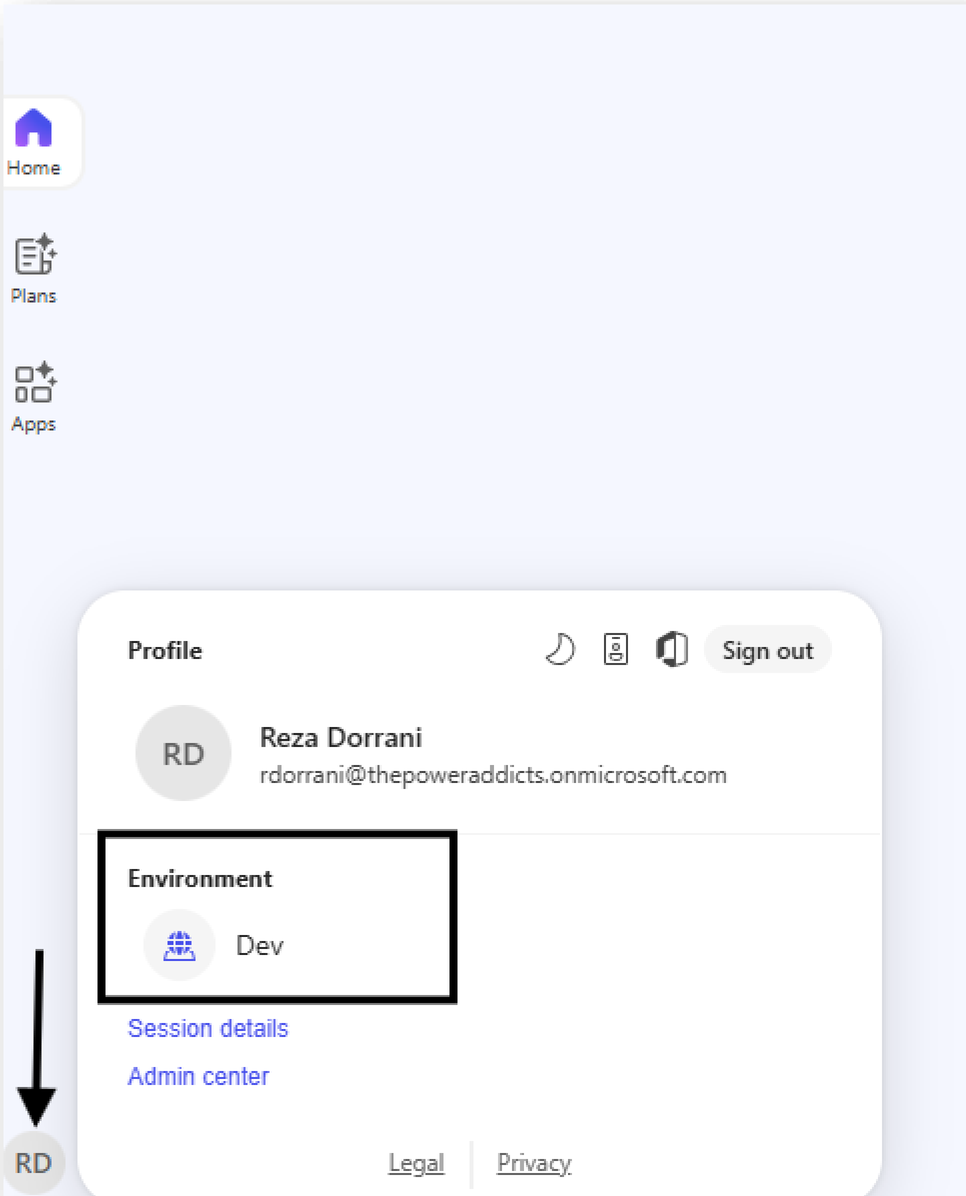


3. Set as preferred solution and Create as shown in image below



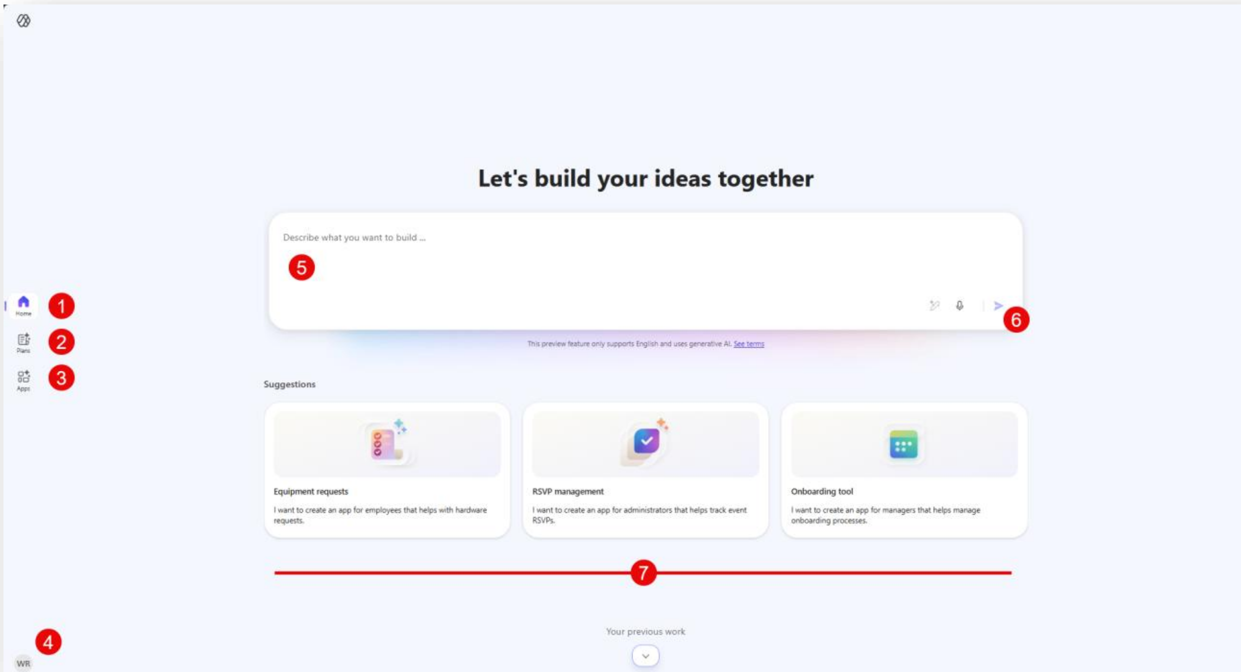
💡 **Note:** When you set a preferred solution, all components generated by Vibe—including plans, code apps, and data assets—are created inside that solution. Any new components created later will also be added automatically in the same solution.

4. Navigate to https://vibe.powerapps.com and confirm the environment name in the bottom-left corner matches the environment where the solution was created.



TIP: Vibe is NOT supported for the Default environment.

5. Review the Vibe home experience, including suggested prompts and navigation options (Home, Plans, Apps).

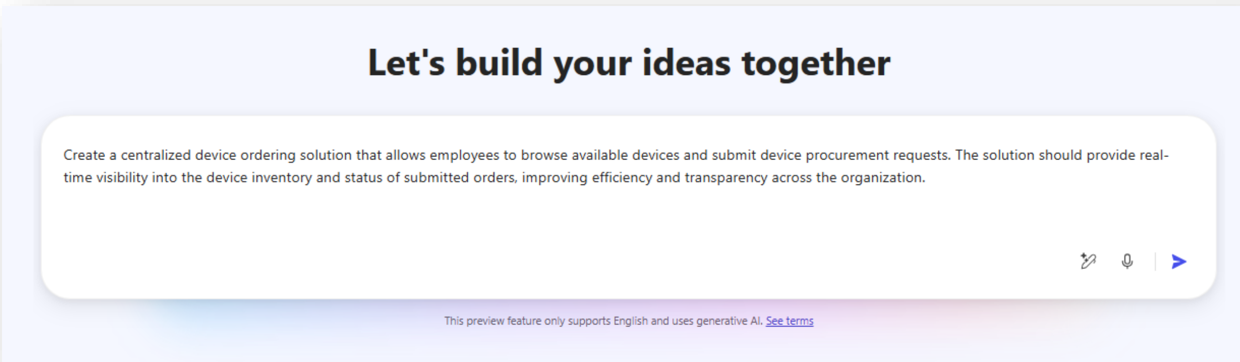


1**: Home page:** This is where you start *vibing*
2: **Plans:** This is where your past plans that you created through vibe live
3: **Apps:** You will find a list of all your vibe created apps here
4: **Profile and Environment Picker:** Review your logged in profile and current environment
5: **Prompt box:** This is where you will enter your prompt to start creating
6: **Submit button:** This kicks off the creation of your Vibe app
7: **Sample Prompts gallery:** Try out sample prompts to check out Vibe

6. Submit the prompt below to Vibe to help generate a device ordering application.

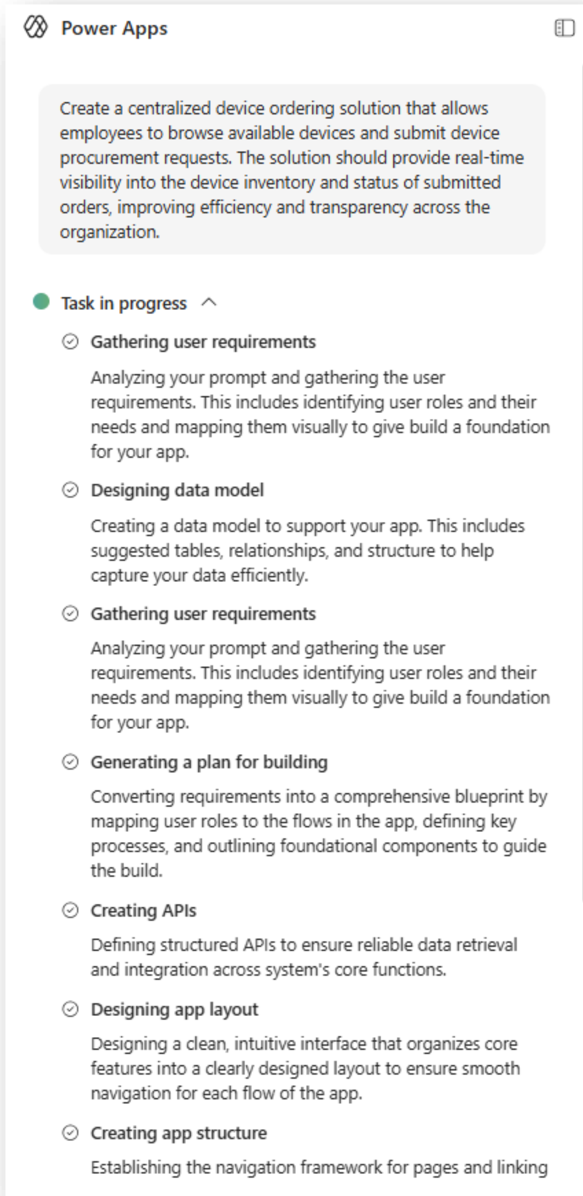
PROMPT:

```
Create a centralized device ordering solution that allows employees to browse
available devices and submit device procurement requests. The solution should
provide real-time visibility into the device inventory and status of
submitted orders, improving efficiency and transparency across the
organization.
```



TIP: Keep prompts high-level. Vibe is designed for iterative refinement.

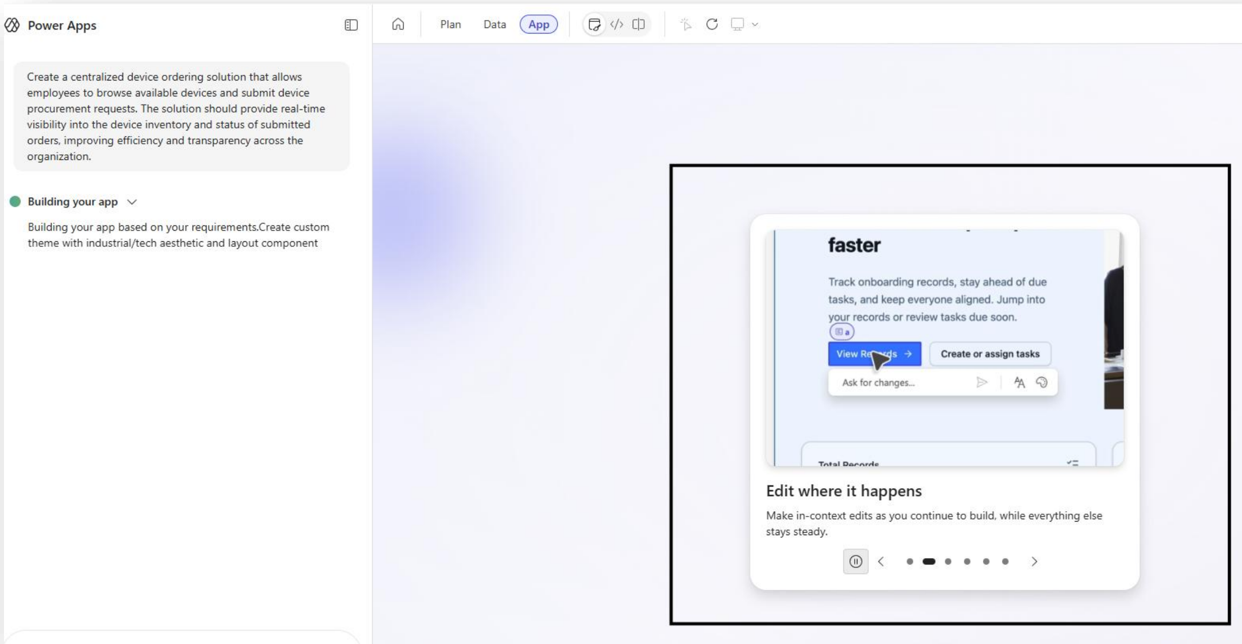
7. Observe the agents on the left-side chat panel as they gather requirements, design the data model, generate a plan, and build the application.



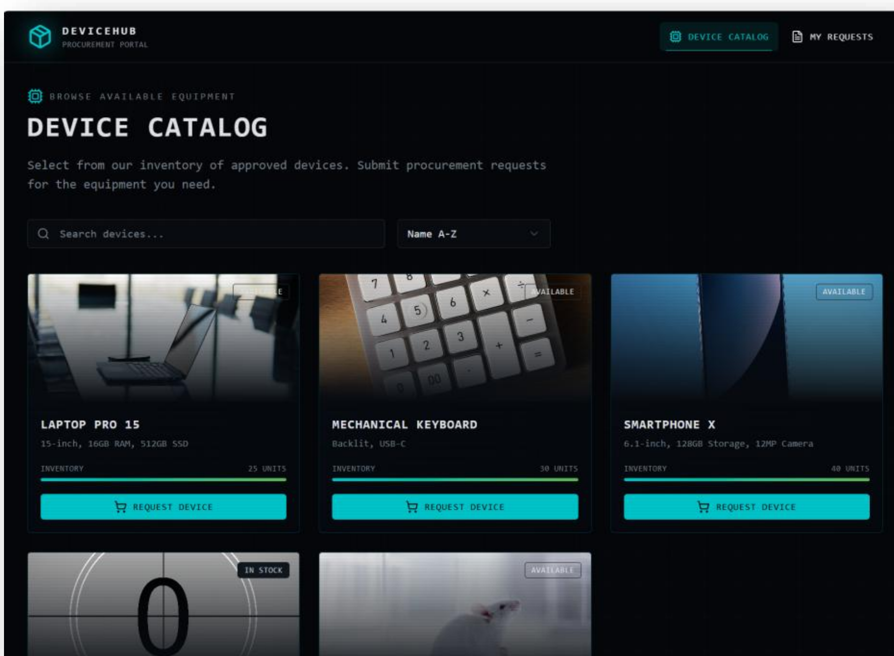
TIPS:

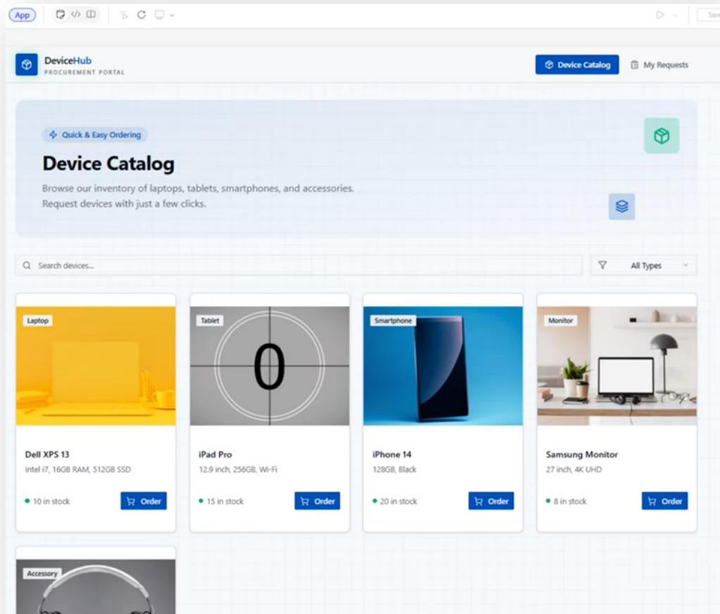
- Make in context edits as you continue to build, while everything else stays steady.
- Small changes add up, and each pass helps move the app closer to what you want.
- Turn on Code view to see how your app is being built without impacting the process.
- Add existing tables from the Data tab and continue shaping how your app works with information.

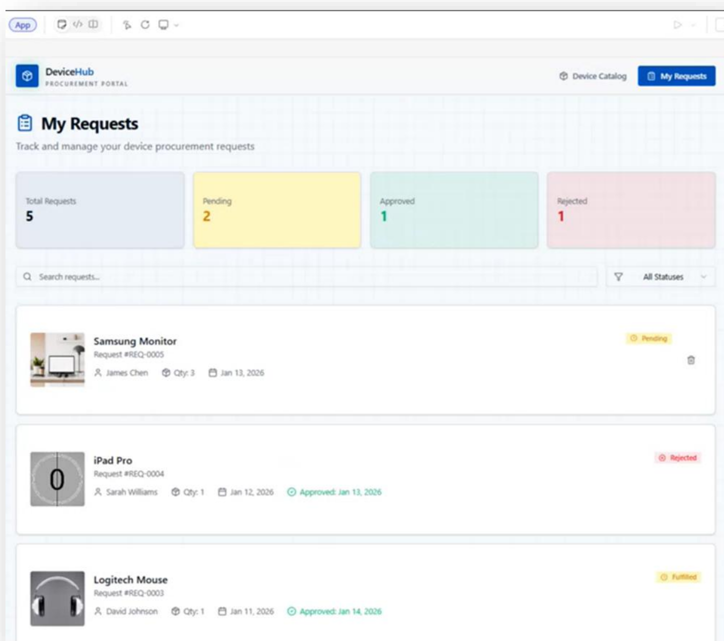
8. The splash widget will showcase the capabilities of the Vibe designer interface while the agents build the plan, data model and React App.



9. Review the generated Device Catalog App (Below is a list of screenshots of variations of App pages generated by Vibe agents)



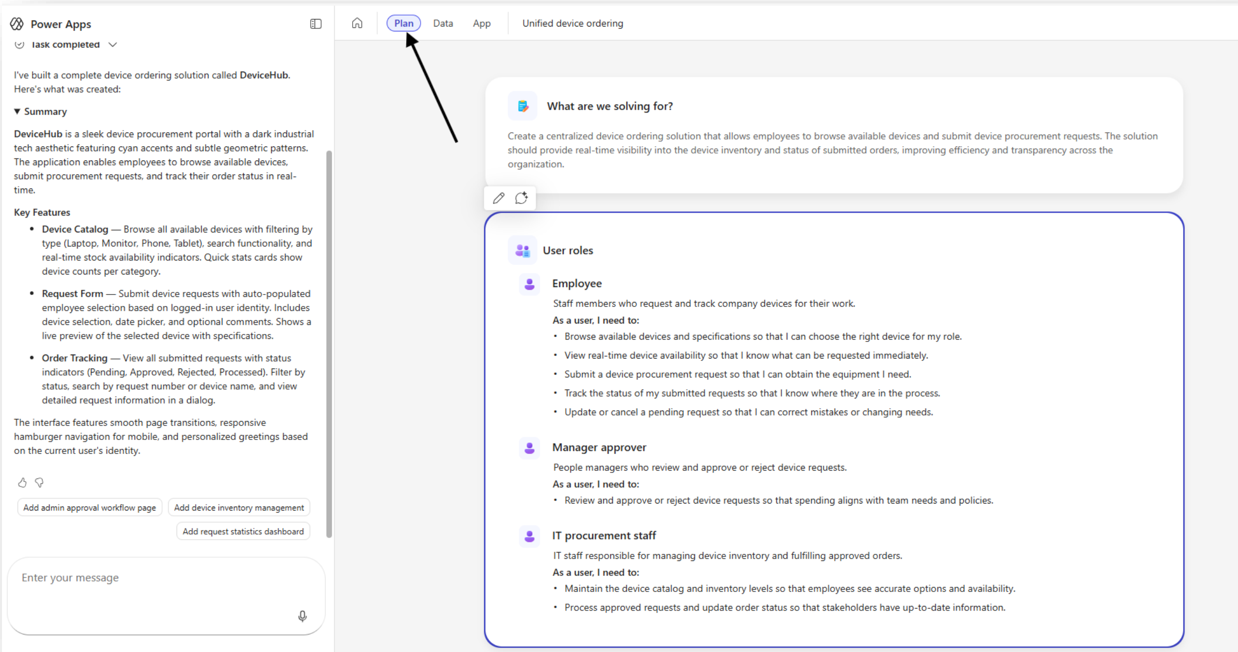




TIP: Apps generated through Generative AI will have variance. This is where iteration is important to get to a state where you have an acceptable outcome.

10. Open the Plan view and review the problem statement, personas, data model, and supporting agents.

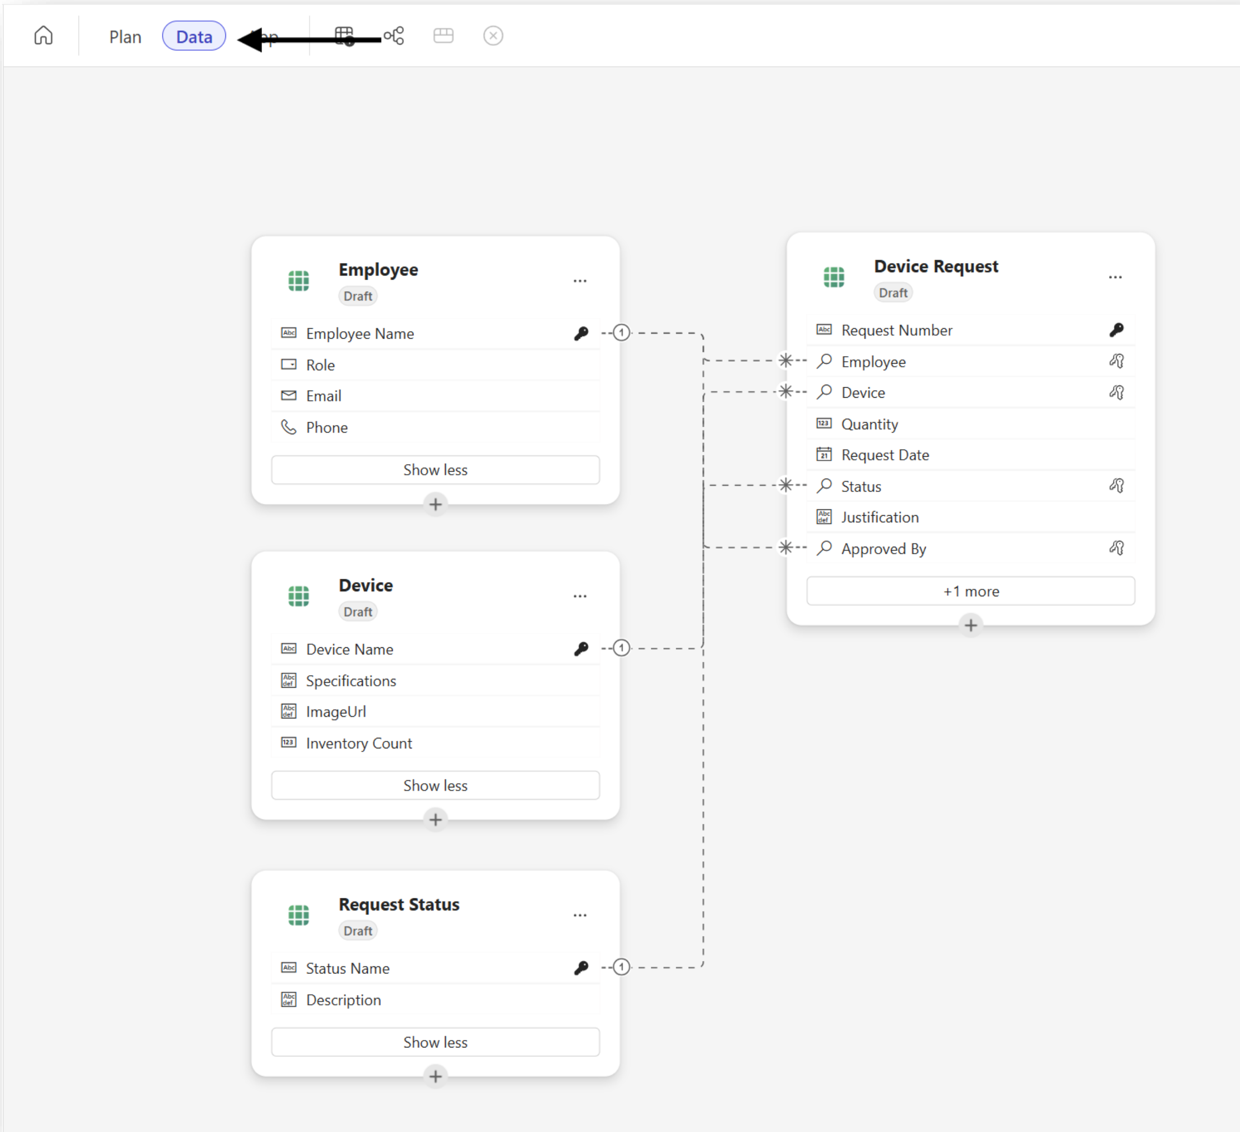
    Note: You can edit User roles, data model to further iterate and align with your business requirements.



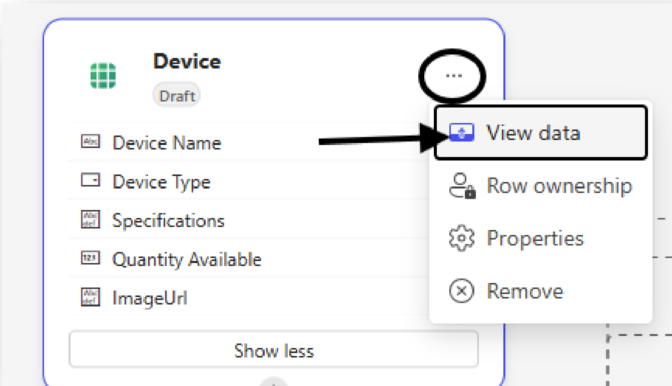
TIP: User roles are conceptual only. Dataverse security roles control access (RBAC) and can be set up after solution is built out.

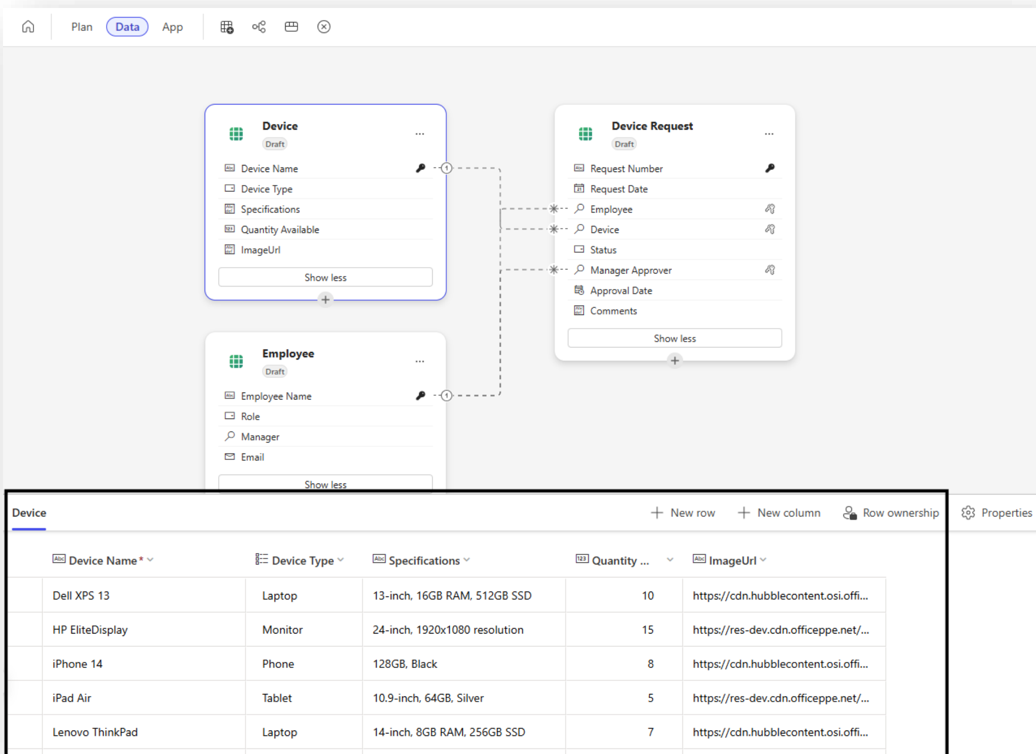
11. Open the Data Model view and review the generated tables and relationships.

    Note: The Data Model generated, including tables, schemas and relationships can vary as this is AI generated. These can be updated with the data agent or manually to align with your business needs.



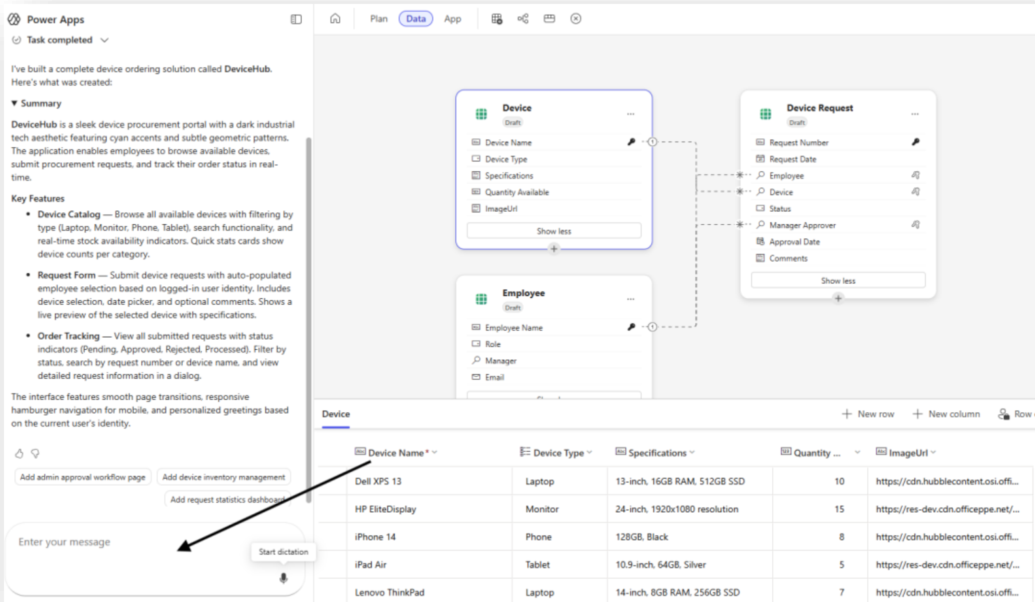
12. Select the Device table. Go to Ellipsis and Select View Data. You would see around 5 rows of sample data, including table columns.

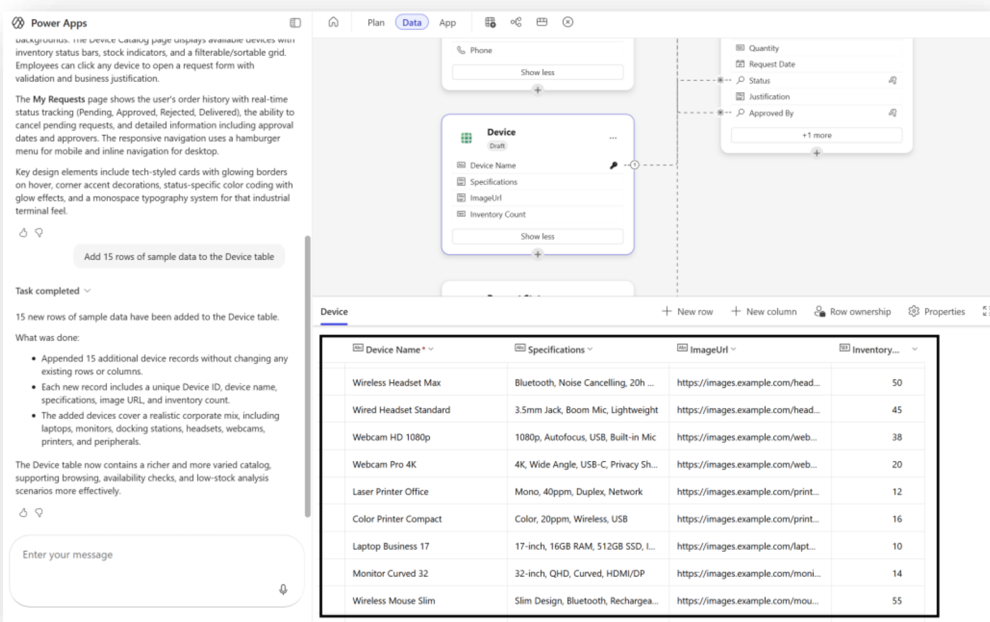




13. Now prompt the agent to add approximately 15 additional rows of sample data.

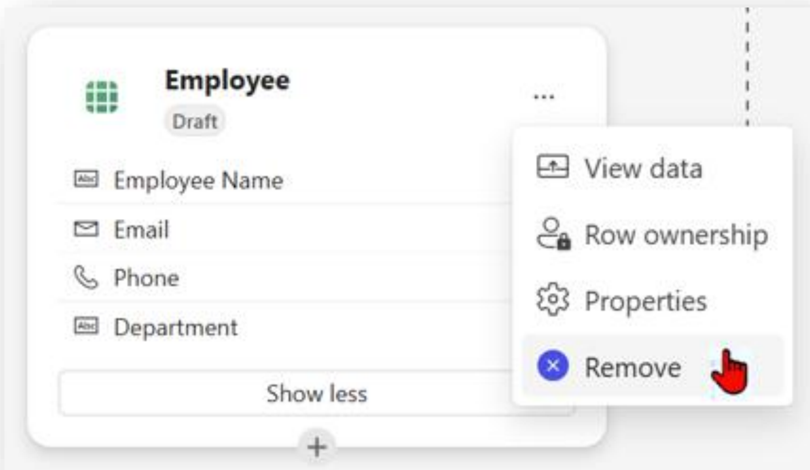
Prompt:
`Add 15 rows of sample data to the Device table`



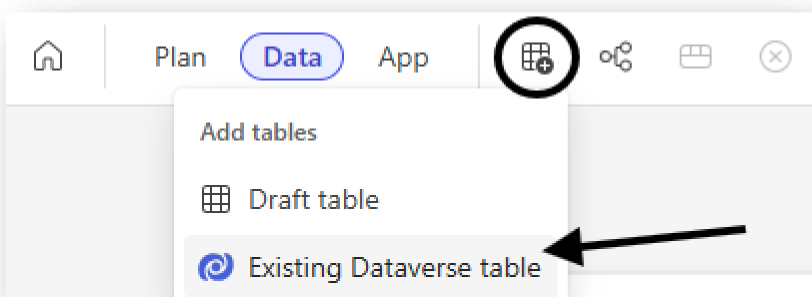


TIP: Sample data is critical for validating UX and business logic during development.

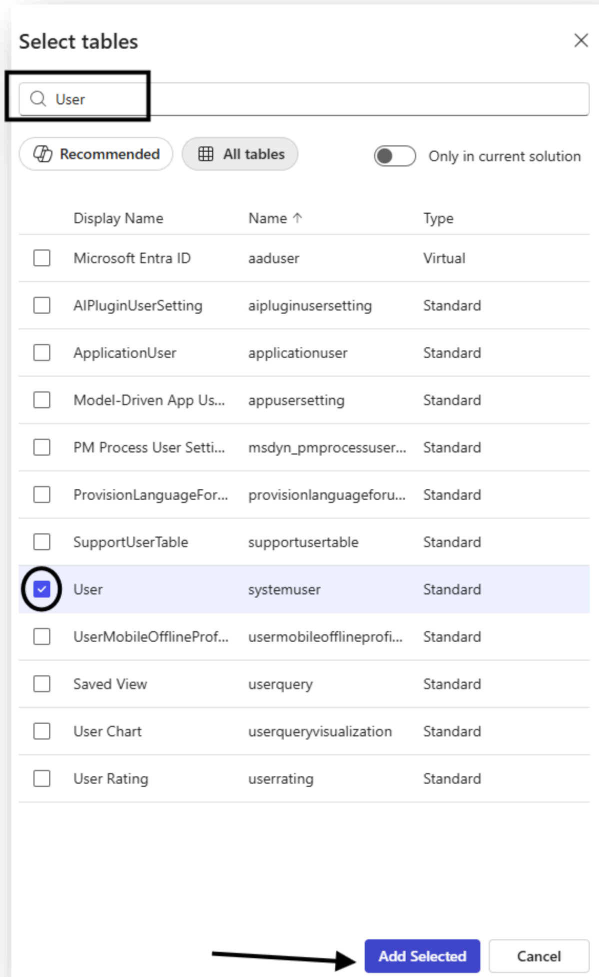
14. Next, we will learn how to bring in data from our existing Dataverse tables. Remove the Employee table



15. Add the existing User table to the model. Select the Add Table icon and then select Existing Dataverse table.



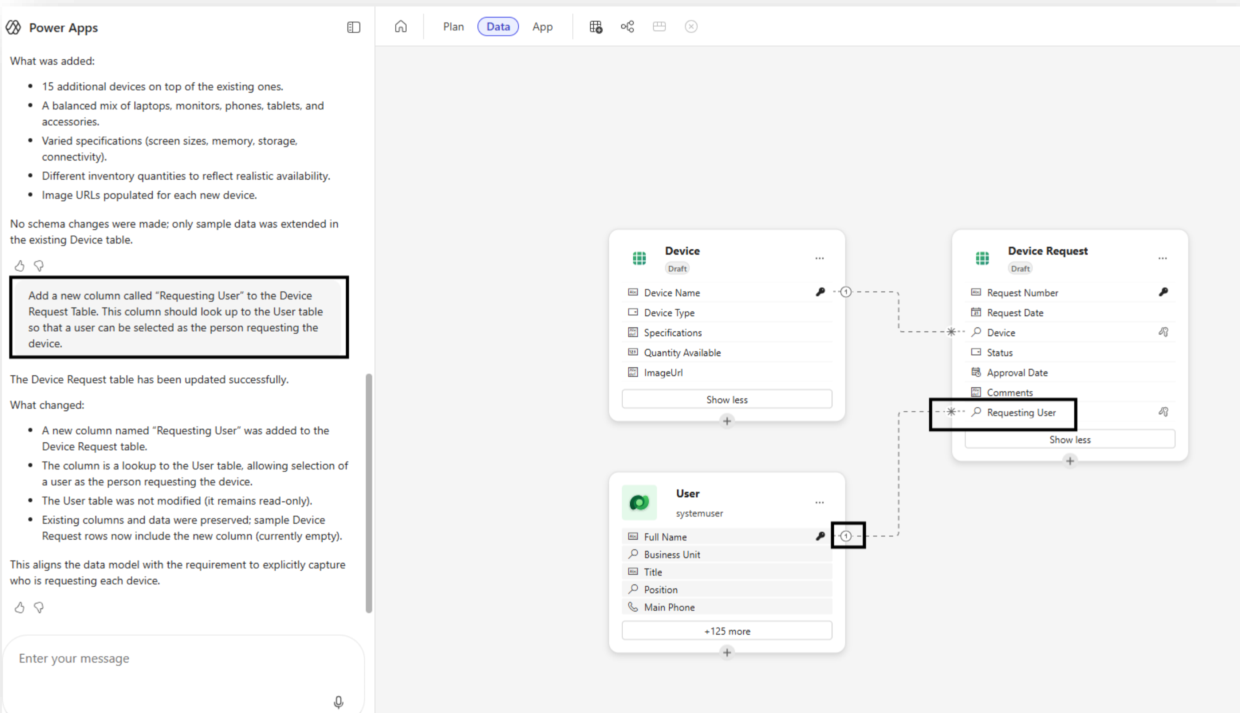
16. This will open Existing Dataverse table list. Search for User table, Select and click on Add Selected button.



17. Add the below prompt to create a relationship between Existing User table and Device Request table.

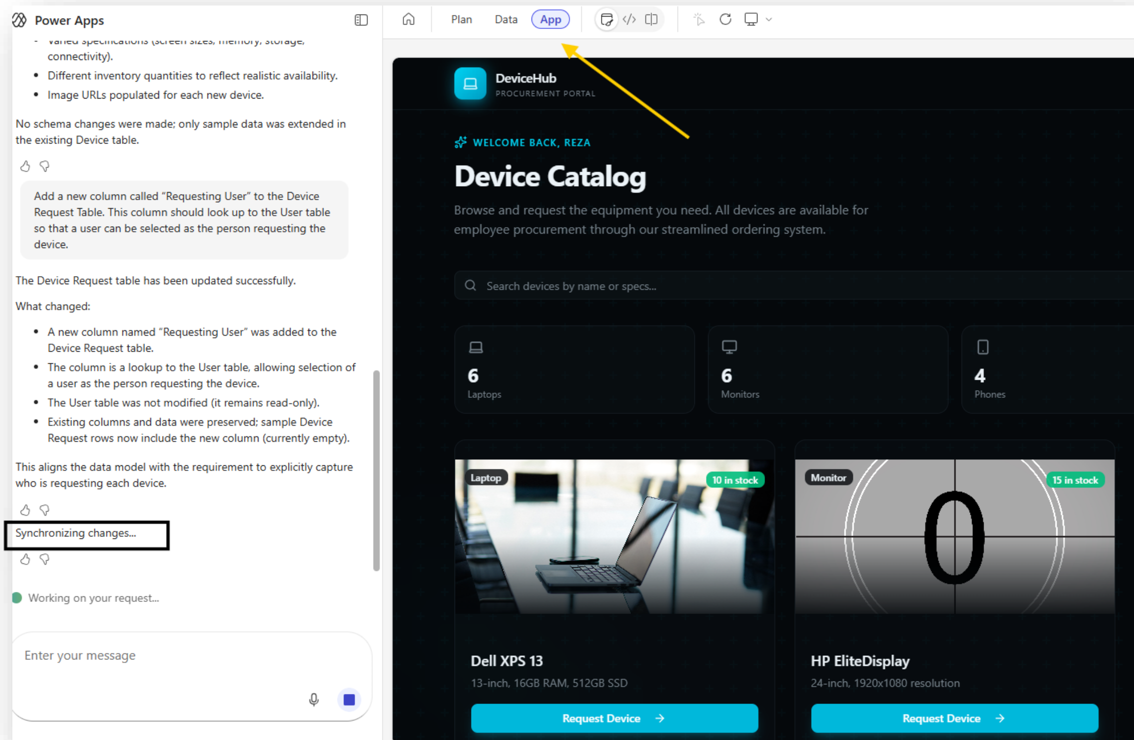
Prompt

```
Add a new column called "Requesting User" to the Device Request Table.
This column should look up to the User table so that a user can be
selected as the person requesting the device.
```



TIP: When you create a 1 to many relationship, a lookup column is added to the Many-side table.

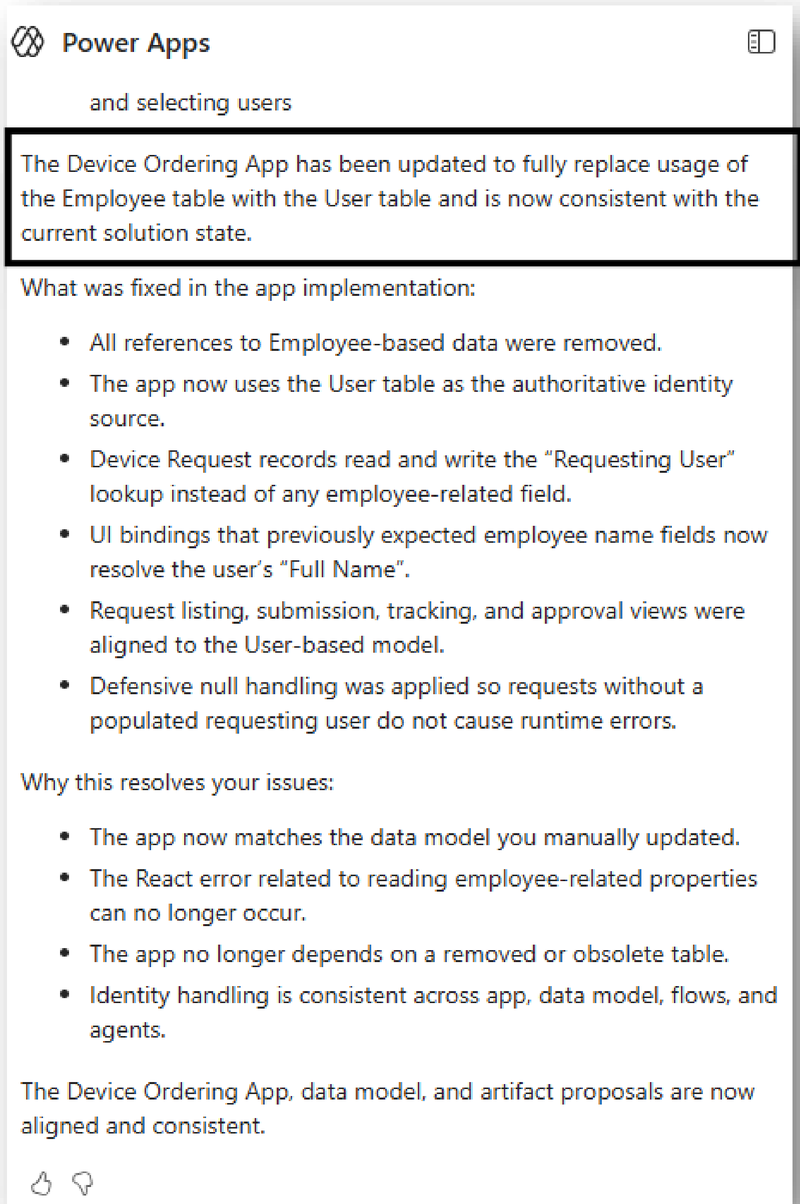
18. After updating the data model, we need to fix the Employee table references in the app. Click on App icon to Synchronize the changes.



19. Now add the following prompt:

Prompt:

```
Update the Device Ordering App artifact to replace Employee Table with
User Table
```

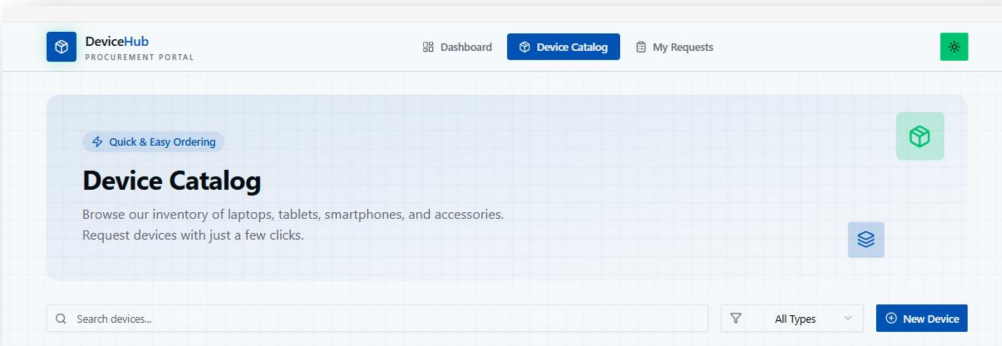


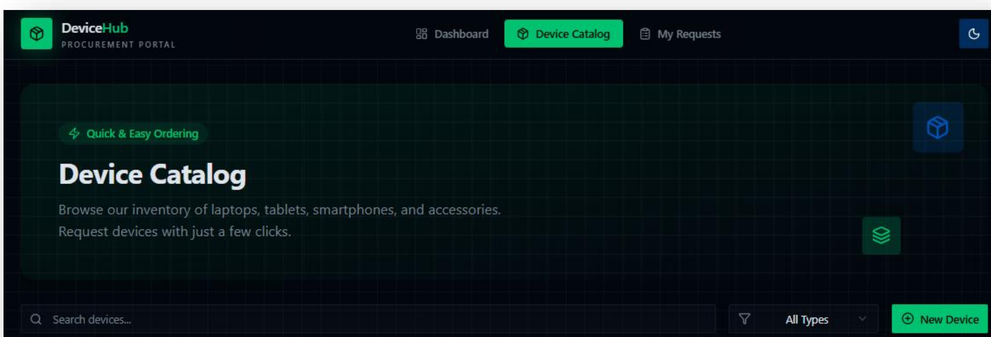
20. Add a light and dark mode toggle using sun and moon icons in the top navigation bar.

Prompt:

```
Add a light/dark mode toggle to the app. Add a toggle button (e.g. a sun/moon
icon) in the top navigation bar that lets the user switch between light and
dark mode.
```

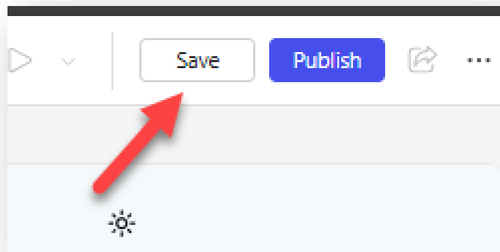
Code agent adds a dark mode button with sun and moon icons:



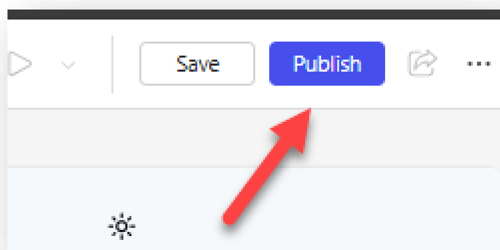


Tip: At any moment, if you want to revert any changes, you can prompt the agent to undo last action.

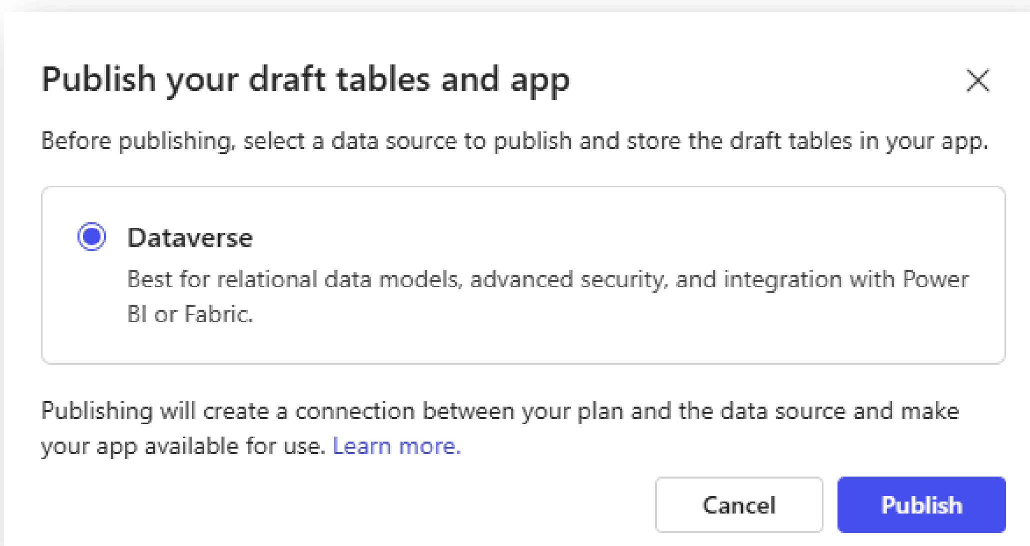
21. Save the application.

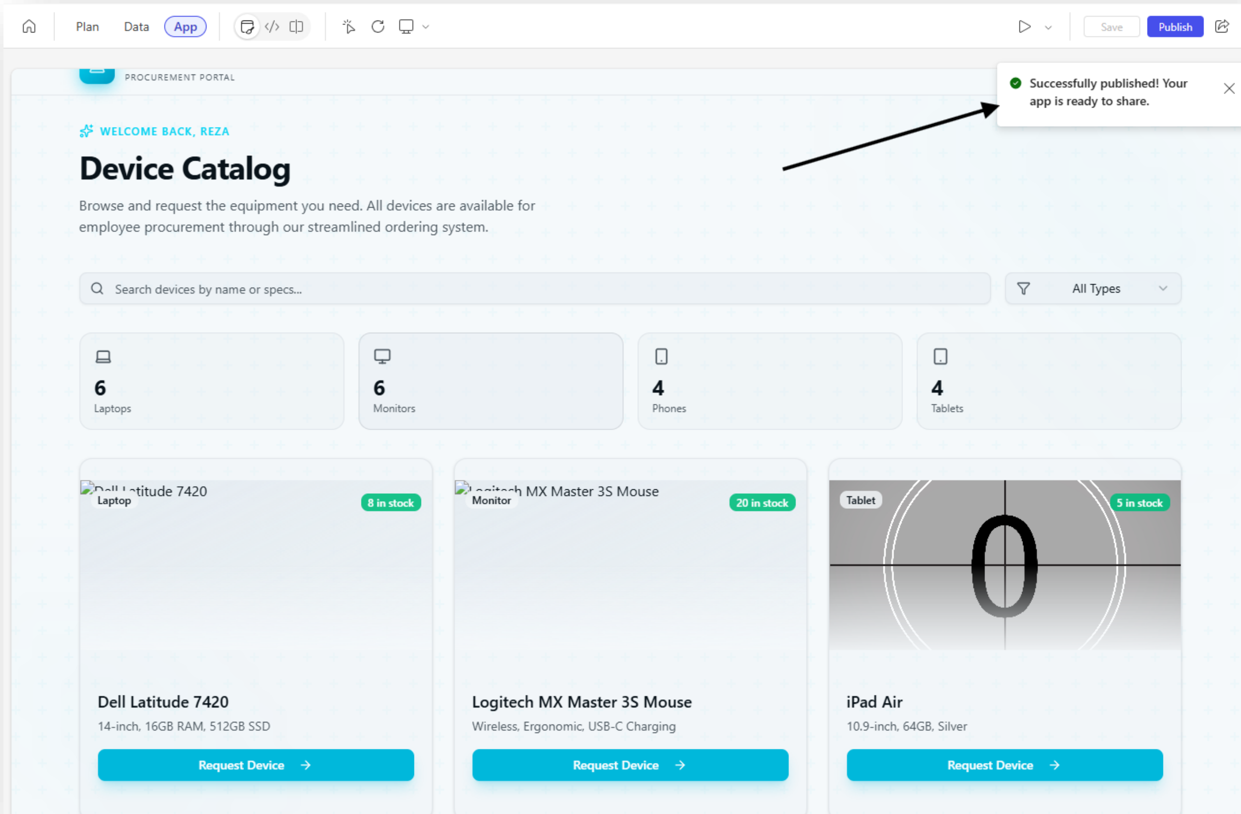


22. Publish the application.



Note: The Draft Tables (newly suggested Tables in data model) will now be Published to Dataverse.



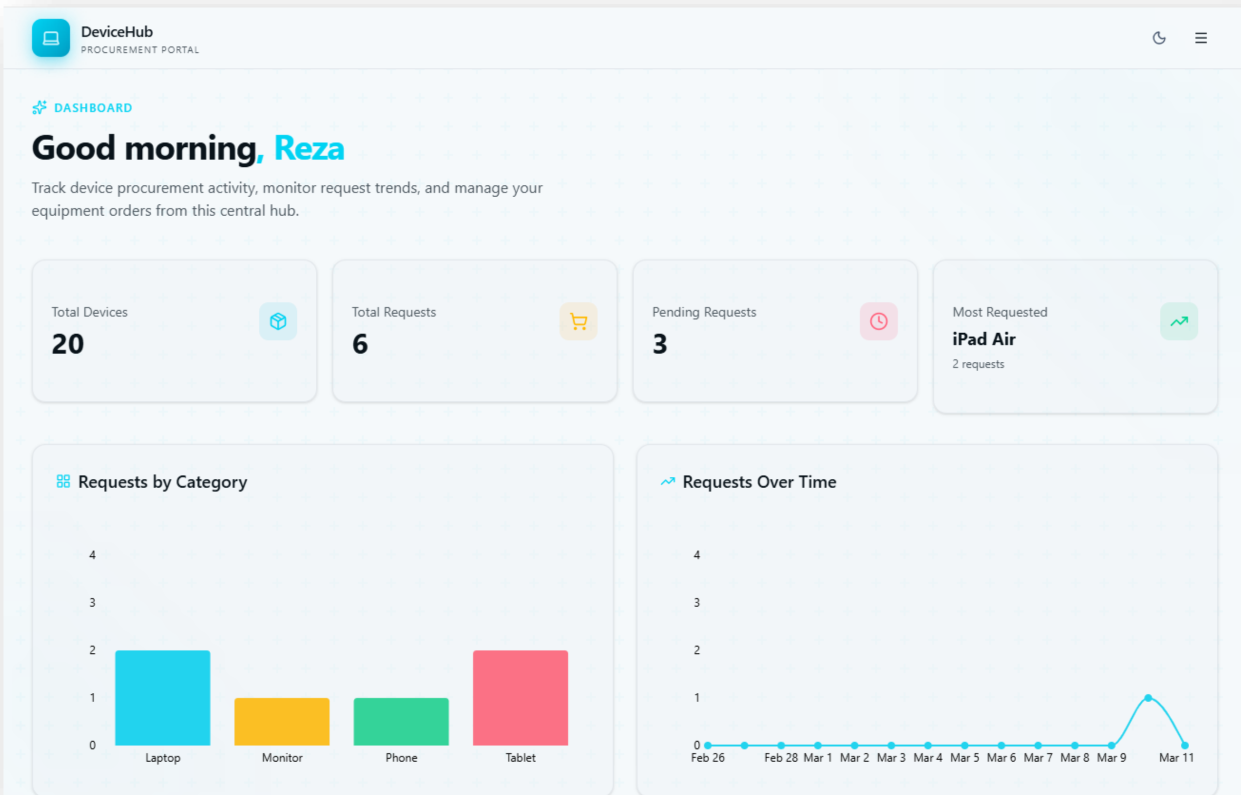


TIP: The first Publish always takes longest as the tables are being created on the Dataverse Schema. Subsequent Publish operations should be much faster.

23. Now let's keep iterating with the agent. Add a dashboard to the application and set it as the default landing page.

PROMPT:

```
Add a dashboard page as the default landing page before the device catalog.
Include summary cards for total devices, total requests, pending requests,
and most requested device. Add a bar chart for requests by category and a
line chart for requests over time.
```

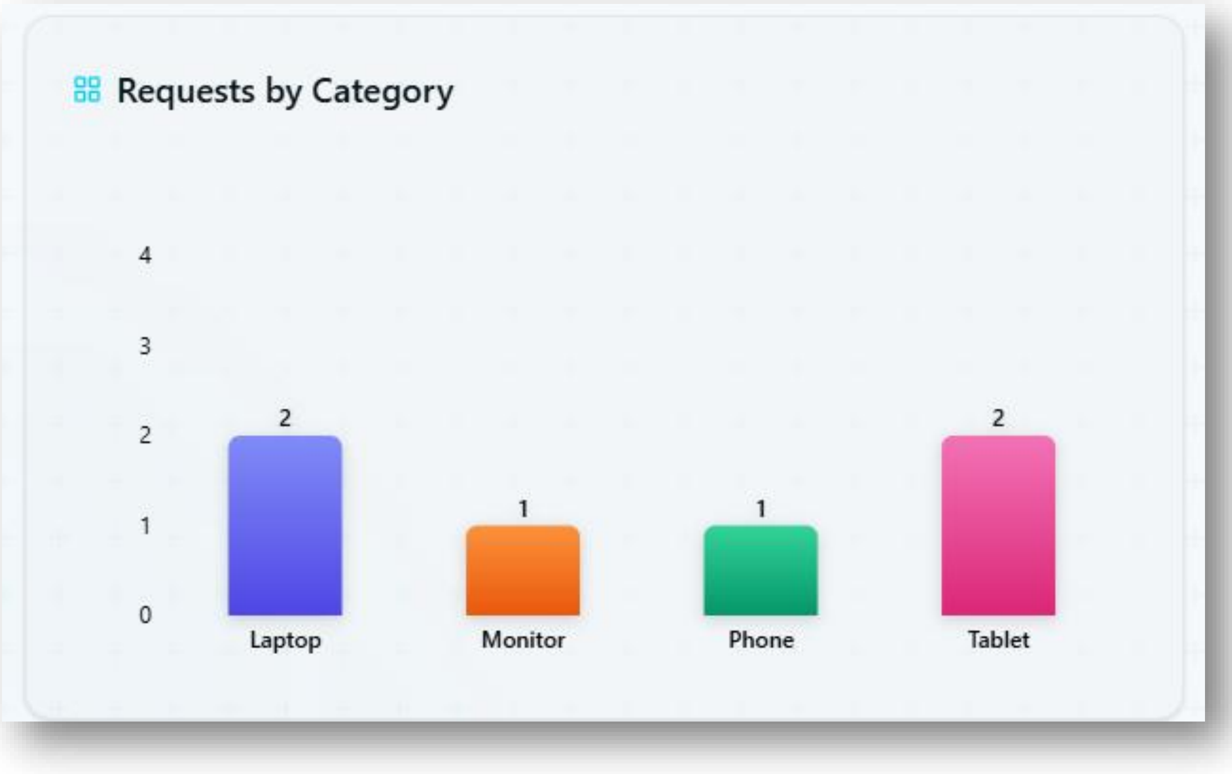


Since the charts were not very vibrant, let's iteratively improve them. This might not be necessary for you if your charts were vibrant and to your liking.

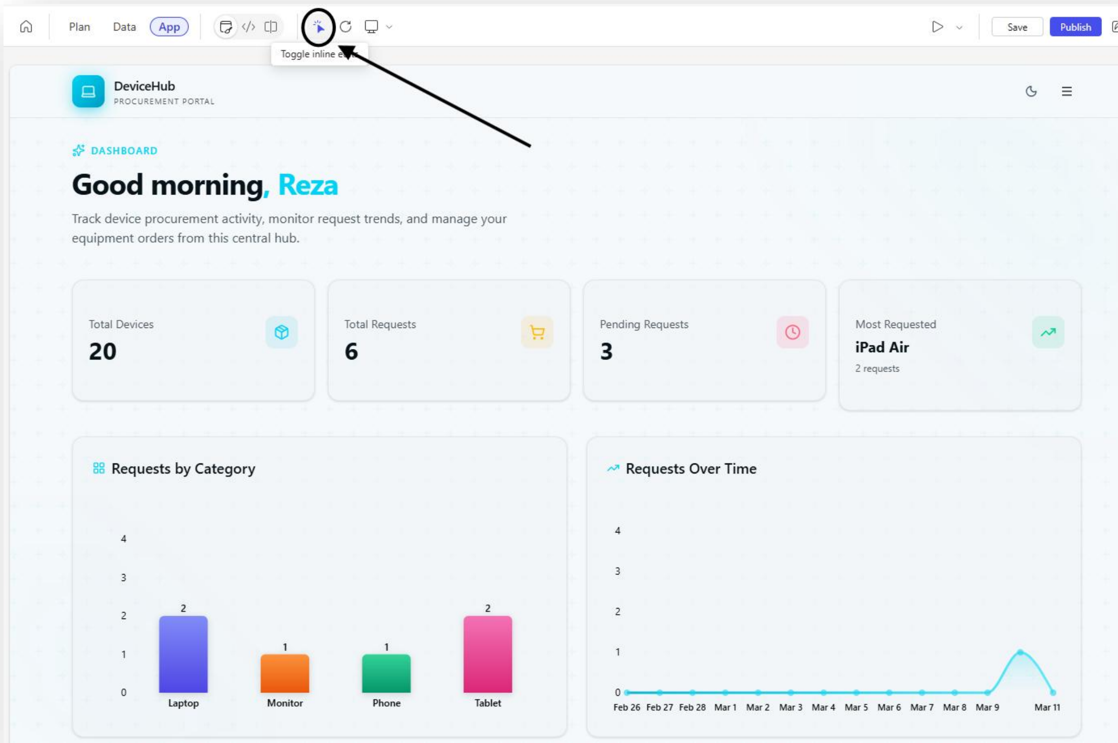
24. Update the bar charts to be more vibrant

Prompt:

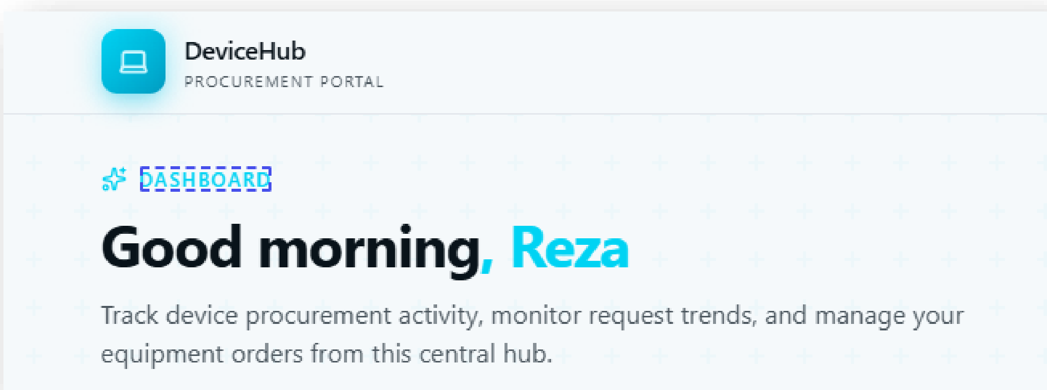
```
Make the Requests by Category chart more colorful. Make sure it is legible
in dark mode as well.
```



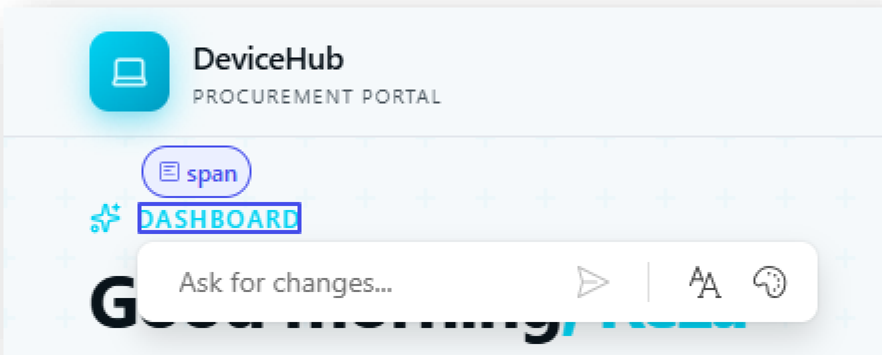
25. Select the Picker tool icon to allow quick inline edits.



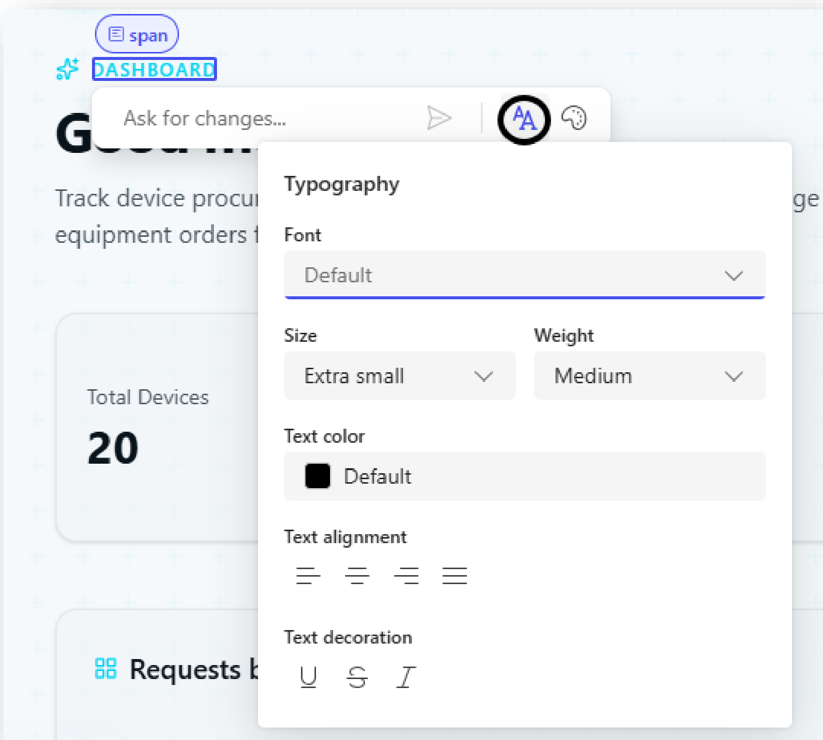
Hover over elements on the page – you will see a border effect for page contents that you can select.



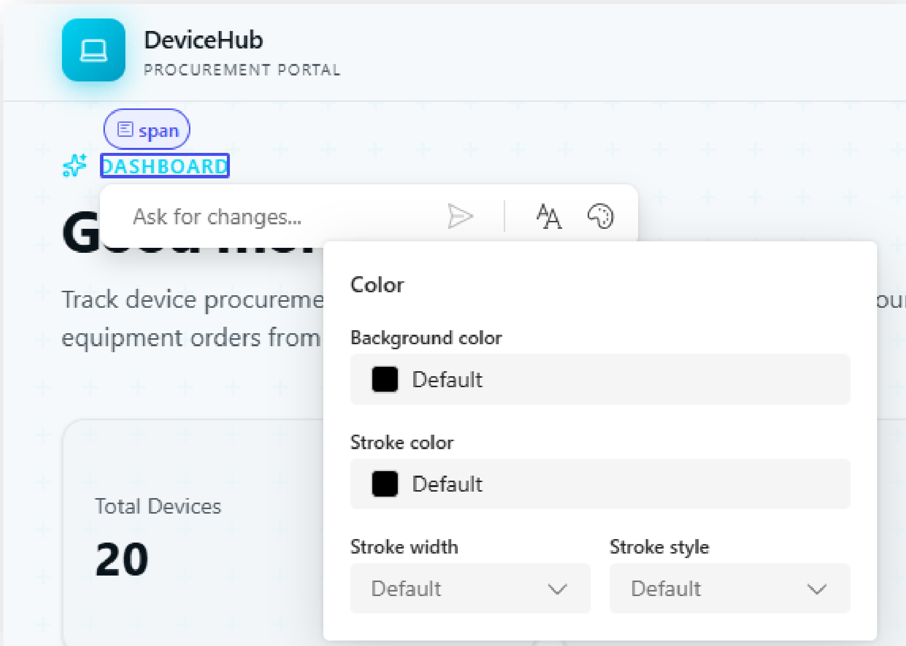
Now select the Dashboard title on your page – you will notice options to ask the agent for changes, changing typography or colors.



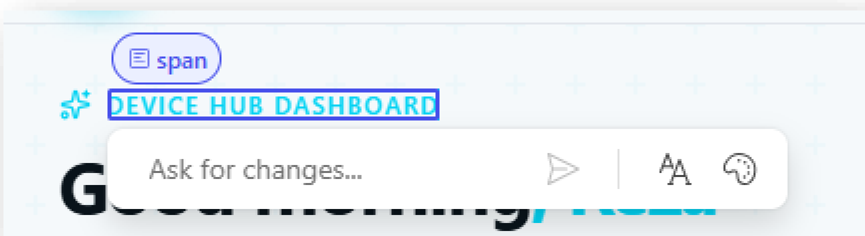
Typography updates



Color updates



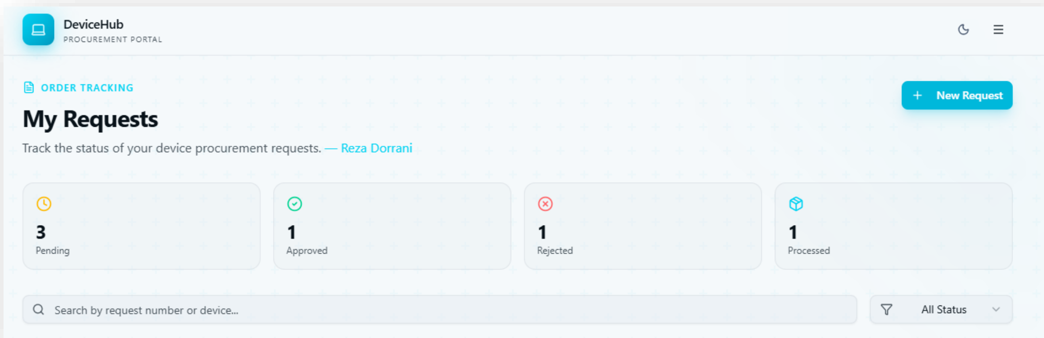
You can also update the text by directly typing in the box as shown below

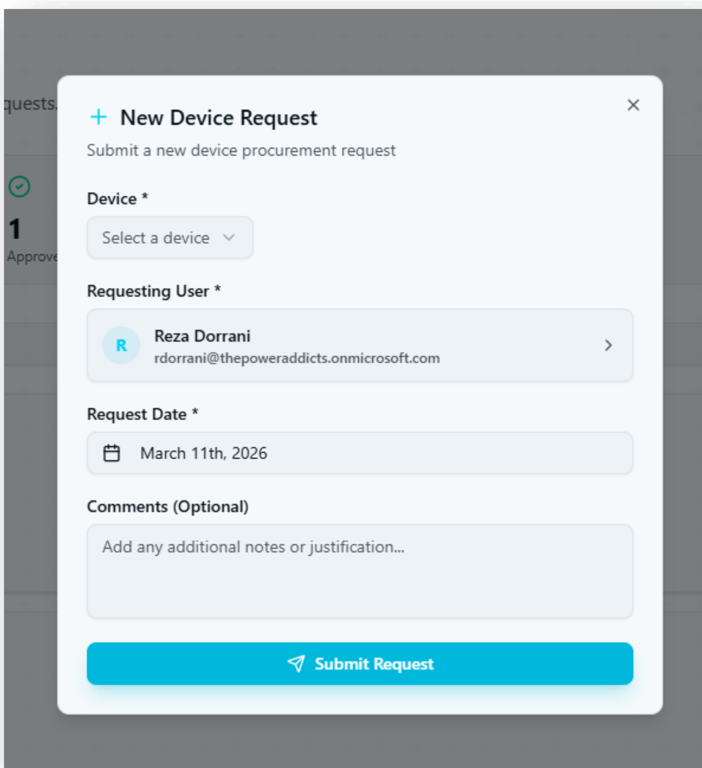


26. Add a New Order button to the My Requests page that opens a form in a dialog box for submitting requests.

Prompt:

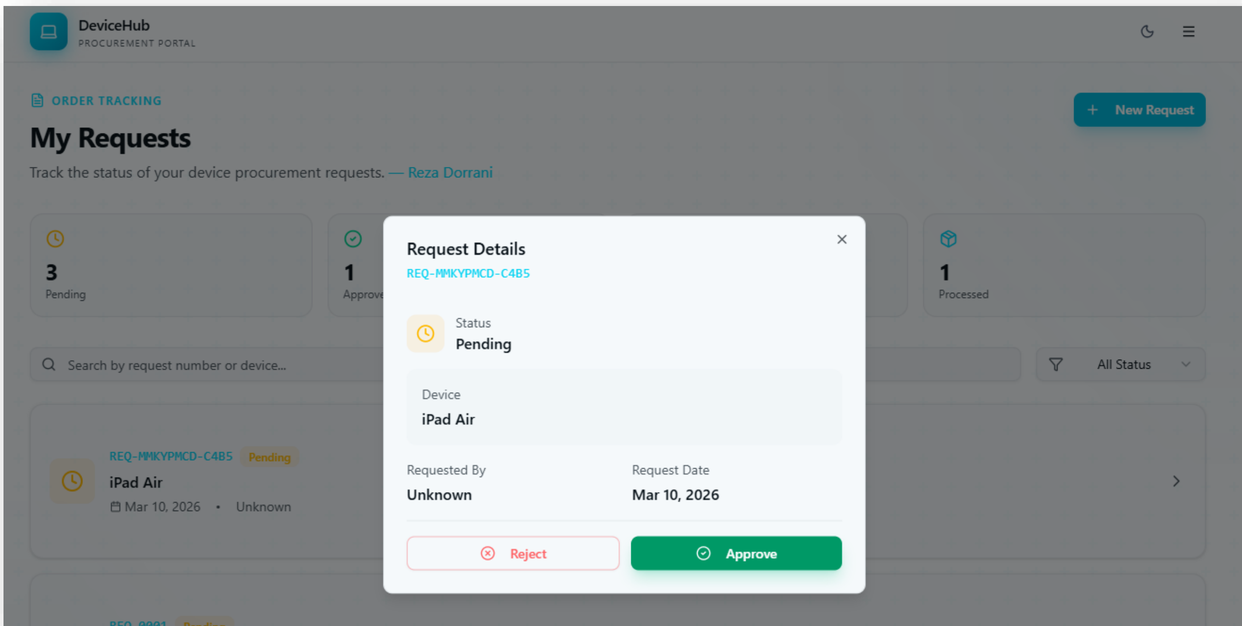
```
Add a "New Request" button on the My Requests page, placed in the top
right area. When clicked, it should open a dialog with a form that lets
the user request a device.
```





27. Add the capability to Approve a pending request and update device inventory if approval is granted.

Prompt:
`Let user approve or reject a pending device request. When clicking on a pending request tile, open a modal dialog which will allow user to review the request. Provide an Approve or Reject button on the bottom of the dialog. If a device request is approved, it should update the available quantity of that device in the device catalog.`

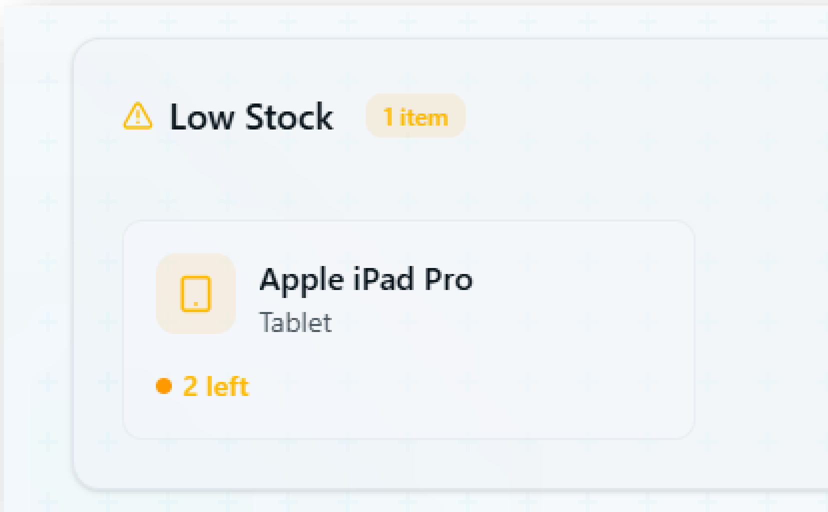


Validate that approving the request results in an update to the available quantity of the device as well.

28. Add a Low Stock Alert grid to the dashboard for devices with fewer than three units available.

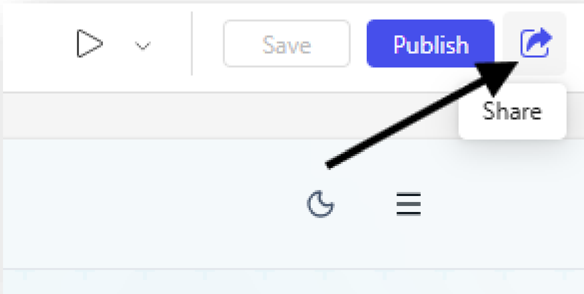
Prompt:

```
Add a Low Stock list view on the Dashboard screen, where any device with
fewer than 3 items on hand are listed. It should sort items by available
quantity, with lowest at the top.
```



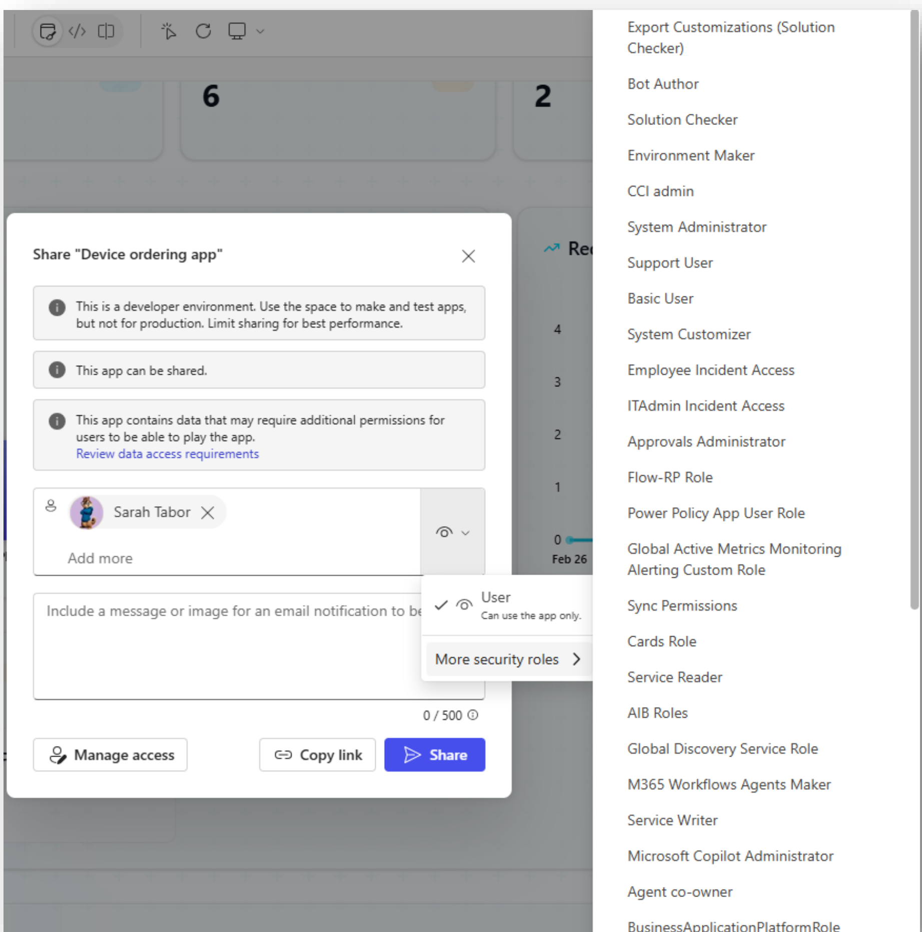
29. Now you can once again Publish your solution.

30. You can click on the Share icon to share app with end users.

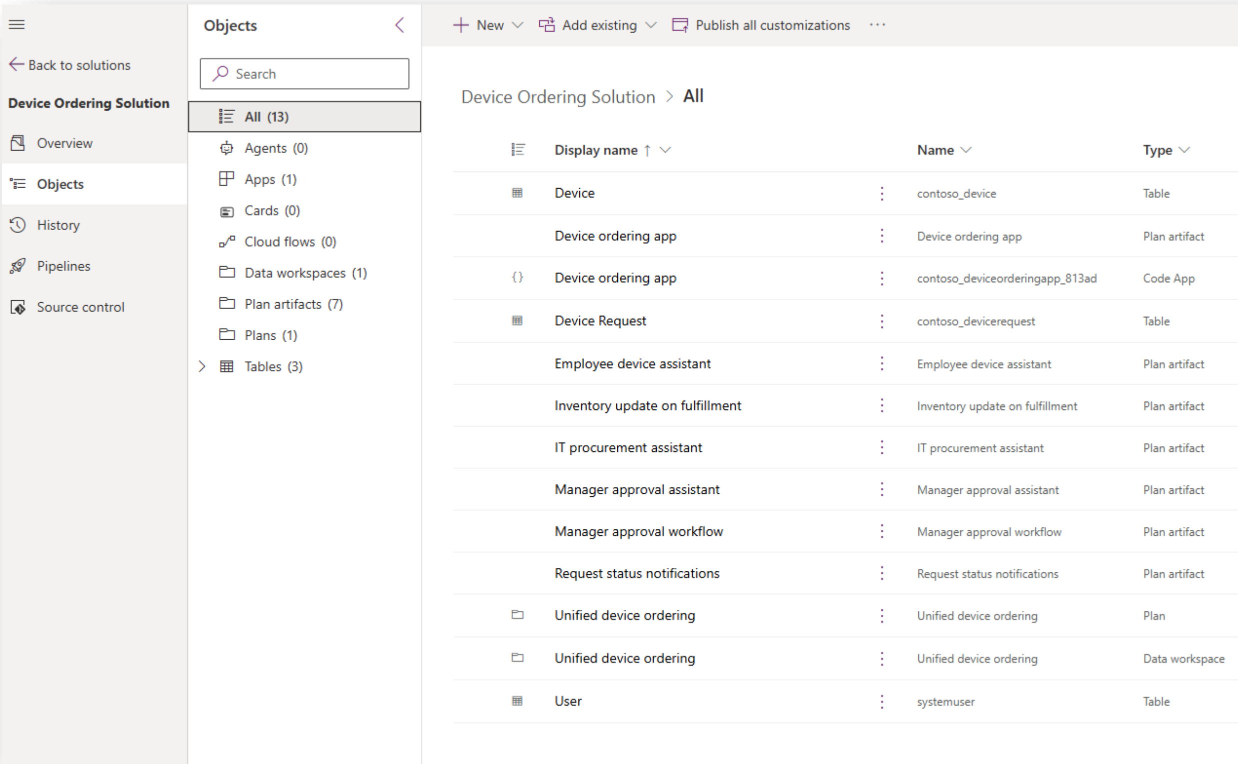


Select users or security groups – also assign security roles.

Tip: You can create custom security roles directly within your solution
[Role-based security roles for Dataverse - Power Platform]



31. If you go back to make.powerapps.com and open your custom solution. You will notice that all the Vibe components, Plan, Plan artifacts etc. are all in solution context. You could now deploy the solution to pipelines to downstream environments, integrate solution with source control and more...



Congratulations!

You've successfully completed the Vibe Power Apps Lab
